

## **Title: Nanometrology for emerging NMIs' needs**

### **Abstract**

The significant progress in recent years in the field of nanotechnologies often involves the production and use of measurement systems whose macroscopic functional properties are determined by phenomena occurring in structures the size of single nanometres. Advanced measurement systems for measurement of dimensional, electrical and mechanical properties based on techniques such as scanning probe microscopy (SPM), feature complex traceability routes and data processing that require significant expertise to implement properly, and this is not always available in many NMIs/DIs. Proposals should focus on the development and increase of nanometrology capabilities of NMIs and DIs that do not yet have the appropriate expertise, but where there are clearly identified stakeholder demands within their countries.

### **Keywords**

Nanometrology, atomic force microscopy (AFM), scanning probe microscopy (SPM), nano-standards, nano-positioning, research potential, traceability.

### **Background to the Metrological Challenges**

Nanotechnology and nanometrology are developing very rapidly, driven by requirements in industries such as automotive, civil engineering, construction, solar technologies, environmental applications, medicine, transportation, agriculture, food processing and textiles. The European Commission has defined industrial Key Enabling Technologies, in which areas of research and innovation are essential to create wellbeing, prosperity and jobs across Europe [3]. Some of the six Key Enabling Technologies, namely advanced manufacturing, advanced materials, micro and nano electronics, and photonics, require appropriate and reliable measurement systems for the nanoscale level. The Consultative Committee for Length (CCL) defined one of the main challenges as nanometrology in its Strategy for 2018-2028 [1]. The European Metrology Network (EMN) for Advanced Manufacturing has identified nano- and microtechnology as a key industrial sector, and has the goal not only to develop measurement systems and metrological methods, but also consequently to improve the quality of production processes [2]. Knowledge transfer and accessibility has been highlighted as a cross cutting theme, which focuses on the requirements for the transfer of metrology knowledge and skills into industrial applications and the metrology community.

In recent years, projects such as NEW05 MechProNO, SIB61 CRYSTAL, 15SIB09 3DNano, 20IND08 MetExSPM funded under European programmes EMRP and EMPIR, provided an opportunity to expand measurement capabilities in the fields of nanotechnology and nanometrology. Whilst many NMIs and universities took advantage of the opportunities in these projects, some were not able to participate due to a lack of relevant experience or an appropriate measuring set-up. Currently, only developed NMIs have measurement equipment that ensures measurement traceability in surface geometry measurements at the nanoscale level. However, industry is also developing dynamically and not only in countries with highly developed or advanced industries, and this causes local industry to seek measurement traceability in another country, thus increasing production costs and extending the production process. Advanced measurement techniques, such as SPM, are also capable of measurement of other properties beyond dimensional e.g. electrical, magnetic, mechanical or thermal properties. Whilst the traceability routes for many of these techniques have already been explored scientifically, they are far from simple and not standard to use, and significant expertise and experience is needed to be able to perform such measurements. The more complex the SPM measurements, the higher is the risk of introducing human errors when setting up the measurement conditions or performing the data processing.

There is therefore a need for a wider range of NMIs/DIs to develop or increase measurement capabilities in nanometrology targeted at identified stakeholders' needs. This requires the development of traceable and cost-effective measurement capabilities for the calibration of nanopositioning systems, and depending on the capabilities required the measurement techniques might be based on AFM, SPM, tactile, optical or laser interferometer systems. It is important that efficient use is made of existing nanometrology capabilities, competence, knowledge and limited resources available, in the development of measurement methods and metrology services. Proposers are therefore encouraged to establish co-operation between NMIs and universities or research organisations to enable this to happen. In addition, the sources of measurement uncertainty for the newly developed nanoscale measurements, nano-positioning systems and nano-standards, need to be estimated, and the new capabilities validated via a comparison in preparation for the submission of Calibration and Measurement Capabilities (CMCs) to the BIPM KCDB.

## Objectives

Proposers should address the objectives stated below, which are based on the PRT submissions. Proposers may identify amendments to the objectives or choose to address a subset of them in order to maximise the overall impact, or address budgetary or scientific / technical constraints, but the reasons for this should be clearly stated in the protocol.

The proposal shall focus the development of metrology capability for nanoscale measurements in NMIs/DIs that are newcomers to this technology, with the aim of supporting the emerging needs of stakeholders.

The specific objectives are:

1. To investigate existing SPMs, nano-standards, software and calibration procedures used to ensure measurement traceability for nanometrology, and to transfer this theoretical and experimental knowledge to the less experienced institutes. In addition, to establish co-operation between NMIs and universities or research organisations to enable efficient use of existing nanometrology capabilities, competence and the limited resources available in the development of measurement methods and metrology services, including the use of SPMs for dimensional measurements, and to investigate the possibility of characterisation of electrical, mechanical and thermal properties.
2. To develop traceable and cost-effective measurement capabilities for the calibration of nano-positioning systems (e.g. SPMs, photomasks, Piezo Displacement Generators) and probe systems (e.g. AFM, tactile) used in nanometrology.
3. To investigate and determine the sources of measurement uncertainty for nanoscale measurements, and to estimate the uncertainties for nano-positioning systems and nano-standards (e.g. line width, height, pitch, grids).
4. To perform an interlaboratory comparison to validate the newly developed nanoscale measurement capabilities, and to underpin improved calibration and measurement capabilities (CMCs) in this field for participating laboratories.
5. To facilitate the take up and long-term operation of the capabilities, technology and measurement infrastructure for nanoscale measurements developed in the project, by the measurement supply chain (NMIs/DIs, calibration and testing laboratories), and end users (e.g. industry, instrument manufacturers, regulators). The approach should be discussed within the consortium and with other EURAMET NMIs/DIs, e.g. via EURAMET TC-L and Advanced Manufacturing EMN, to ensure that a coordinated and optimised approach to the development of traceability in this field is developed for Europe as a whole.

Joint Research Proposals submitted against this SRT should identify

- the particular metrology needs of stakeholders in the region,
- the research capabilities that should be developed (as clear technical objectives),
- the area for which the capabilities will be built (Green Deal, Digital Transformation, Health, Integrated European Metrology, Industry, Normative or Fundamental Metrology) and in which future main call the developed research capabilities are planned to be employed,
- the impact the developed research capabilities will have on the industrial competitiveness and societal needs of the region,
- how the research capability will be sustained and further developed after the project ends.

Proposers should establish the current state of the art and explain how their proposed research goes beyond this. In particular, proposers should outline the achievements of the EMRP and EMPIR project(s) NEW05 MechProNO, SIB61 CRYSTAL, 15SIB09 3DNano, 20IND08 MetExSPM, and how their proposal will build on those.

The development of the research potential should be to a level that would enable participation in other TPs.

Proposers should note that the programme funds the activity of researchers to develop the capability, not the required infrastructure and capital equipment, which must be provided from other sources.

EURAMET expects the average EU Contribution for the selected JRPs in this TP to be 0.7 M€ and has defined an upper limit of 0.9 M€ for this proposal.

EURAMET also expects the EU Contribution to the external funded beneficiaries to not exceed 20 % of the total EU Contribution across all selected projects in this TP.

Any industrial beneficiaries that will receive significant benefit from the results of the proposed project are expected to be beneficiaries without receiving funding or associated partners.

## Potential Impact

Proposals must demonstrate adequate and appropriate participation/links to the 'end user' community, describing how the project partners will engage with relevant communities during the project to facilitate knowledge transfer and accelerate the uptake of project outputs. Evidence of support from the "end user" community (e.g. letters of support) is also encouraged.

You should detail how your proposal's results are going to:

- Address the SRT objectives and deliver solutions to the documented needs,
- Provide a lasting improvement in the European metrological capability and infrastructure beyond the lifetime of the project,
- Facilitate improved industrial capability or improved quality of life for European citizens in terms of personal health, protection of the environment and the climate, or energy security,
- Transfer knowledge to the advanced manufacturing and nanotechnology sectors and the metrology community.

You should detail other impacts of your proposed JRP as specified in the document "Guide 4: Writing Joint Research Projects (JRPs)"

You should also detail how your approach to realising the objectives will further the aim of the Metrology Partnership to develop a coherent approach at the European level in the field of metrology and include the best available contributions from across the metrology community. Specifically, the opportunities for:

- improvement of the efficiency of use of available resources to better meet metrological needs and to assure the traceability of national standards
- the metrology capacity of EURAMET Member States whose metrology programmes are at an early stage of development to be increased
- organisations other than NMIs and DIs to be involved in the work.

## Timescale

The project should be of up to 3 years duration.
